This code was originally written for CS 231n at Stanford University
(cs231n.stanford.edu). It has been modified in various areas for use in the
ECE 239AS class at UCLA. This includes the descriptions of what code to
implement as well as some slight potential changes in variable names to be
consistent with class nomenclature. We thank Justin Johnson & Serena Yeung for
permission to use this code. To see the original version, please visit
cs231n.stanford.edu.
class TwoLayerNet(object):
    A two-layer fully-connected neural network. The net has an input dimension of
    N, a hidden layer dimension of H, and performs classification over C classes.
    We train the network with a softmax loss function and L2 regularization on the
    weight matrices. The network uses a ReLU nonlinearity after the first fully
    connected layer.
    In other words, the network has the following architecture:
    input - fully connected layer - ReLU - fully connected layer - softmax
    The outputs of the second fully-connected layer are the scores for each class.
    def __init__(self, input_size, hidden_size, output_size, std=le-4):
        Initialize the model. Weights are initialized to small random values and
        biases are initialized to zero. Weights and biases are stored in the
        variable self.params, which is a dictionary with the following keys:
        W1: First layer weights; has shape (H, D)
        b1: First layer biases; has shape (H,)
        W2: Second layer weights; has shape (C, H)
        b2: Second layer biases; has shape (C,)
        - input size: The dimension D of the input data.
        - hidden size: The number of neurons H in the hidden layer.
        - output size: The number of classes C.
        self.params = {}
        self.params["W1"] = std * np.random.randn(hidden_size, input_size)
        self.params["b1"] = np.zeros(hidden size)
        self.params["W2"] = std * np.random.randn(output_size, hidden_size)
        self.params["b2"] = np.zeros(output_size)
    def loss(self, X, y=None, reg=0.0):
        Compute the loss and gradients for a two layer fully connected neural
        network.
        Inputs:
        - X: Input data of shape (N, D). Each X[i] is a training sample.
        - y: Vector of training labels. y[i] is the label for X[i], and each y[i] is
          an integer in the range 0 \le y[i] \le C. This parameter is optional; if it
          is not passed then we only return scores, and if it is passed then we
          instead return the loss and gradients.
        - reg: Regularization strength.
        Returns:
        If y is None, return a matrix scores of shape (N, C) where scores[i, c] is
        the score for class c on input X[i].
        If y is not None, instead return a tuple of:
        - loss: Loss (data loss and regularization loss) for this batch of training
          samples.
```

- grads: Dictionary mapping parameter names to gradients of those parameters

```
with respect to the loss function; has the same keys as self.params.
# Unpack variables from the params dictionary
W1, b1 = self.params["W1"], self.params["b1"]
W2, b2 = self.params["W2"], self.params["b2"]
N, D = X.shape
# Compute the forward pass
scores = None
# YOUR CODE HERE:
   Calculate the output scores of the neural network. The result
   should be (N, C). As stated in the description for this class,
     there should not be a ReLU layer after the second FC layer.
     The output of the second FC layer is the output scores. Do not
     use a for loop in your implementation.
h1 = np.maximum(np.dot(X, W1.T) + b1, 0)
scores = np.dot(h1, W2.T) + b2
# END YOUR CODE HERE
# If the targets are not given then jump out, we're done
if y is None:
   return scores
# Compute the loss
loss = None
# YOUR CODE HERE:
  Calculate the loss of the neural network. This includes the
     softmax loss and the L2 regularization for W1 and W2. Store the
     total loss in teh variable loss. Multiply the regularization
     loss by 0.5 (in addition to the factor reg).
# scores is num examples by num classes
exp scores = np.exp(scores)
loss = (
  np.sum(np.log(np.sum(exp scores, axis=1)) - scores[np.arange(N), y]) / N
) + 0.5 * reg * (np.linalg.norm(W1) ** 2 + np.linalg.norm(W2) ** 2)
# END YOUR CODE HERE
grads = {}
# YOUR CODE HERE:
      Implement the backward pass. Compute the derivatives of the
     weights and the biases. Store the results in the grads
     dictionary. e.g., grads['W1'] should store the gradient for
     W1, and be of the same size as W1.
